# Topics list

---

- Why arrays?
- Primitive Arrays
- Array Syntax

# Why arrays?

---

- We look at different pieces of code to explain the concept.
- In each piece of code, we:
  - read in 10 numbers from the keyboard
  - add the numbers
  - print the sum of all the numbers.

# Adding 10 numbers

```
import javax.swing.JOptionPane;
```

```
int n;
```

```
int sum = 0;
```

Reads in 10 numbers  
from the keyboard

```
for (int i = 0; i < 10; i++) {
```

```
    n = Integer.parseInt
```

```
        (JOptionPane.showInputDialog(
```

```
            "Please enter a number ", "3"));
```

```
    sum += n;
```

```
}
```

```
println("The sum of the values you typed in is : " + sum);
```

# Adding 10 numbers

```
import javax.swing.JOptionPane;
```

```
int n;  
int sum = 0;
```

```
for (int i = 0; i<10; i++) {  
    n = Integer.parseInt  
        (JOptionPane.showInputDialog(  
            "Please enter a number ", "3"));
```

```
    sum += n;
```

```
}
```

```
println("The sum of the values you typed in is : " + sum);
```

As each number is entered,  
it is added to the value  
currently stored in **sum**.

# Adding 10 numbers

```
import javax.swing.JOptionPane;
```

```
int n;
```

```
int sum = 0;
```

```
for (int i = 0; i<10; i++) {
```

```
    n = Integer.parseInt
```

```
        (JOptionPane.showInputDialog(
```

```
            "Please enter a number ", "3"));
```

```
    sum += n;
```

```
}
```

When the 10 numbers  
have been read in,  
the **sum** of the 10 numbers  
is printed to the console.

```
println("The sum of the values you typed in is : " + sum);
```

# Adding 10 numbers

```
import javax.swing.JOptionPane;
```

```
int n;  
int sum = 0;
```

```
for (int i = 0; i < 10; i++) {  
    n = Integer.parseInt  
        (JOptionPane.showInputDialog(  
            "Please enter a number ", "3"));
```

```
    sum += n;
```

```
}
```

```
println("The sum of the values you typed in is : " + sum);
```

Notice that,  
each time a number is read in,  
it overwrites the value stored in **n**.

It doesn't remember  
the individual numbers typed in.

# Rule – Never lose input data

---

- Always try to **store** input data for later use
- In real-life systems,  
you nearly always need to use it again.
- The previous code has NOT done this.
  - Let's try another way ...

# Remembering the Numbers

---

This works in the sense that we have retained the input data.

```
int n0,n1, n2, n3, n4, n5, n6, n7, n8, n9;  
int sum = 0;
```

```
n0 = Integer.parseInt (JOptionPane.showInputDialog("Please enter a number ", "3"));  
sum += n0;
```

```
n1 = Integer.parseInt (JOptionPane.showInputDialog("Please enter a number ", "3"));  
sum += n1;
```

```
//rest of code for n2 to n8
```

```
n9= Integer.parseInt(JOptionPane.showInputDialog("Please enter a number ", "3"));  
sum += n9;
```

```
println("The sum of the values you typed in is : " + sum);
```

# Remembering the Numbers

---

```
int n0,n1, n2, n3, n4, n5, n6, n7, n8, n9;  
int sum = 0;  
  
n0 = Integer.parseInt(JOptionPane.showInputDialog());  
sum += n0;  
  
n1 = Integer.parseInt(JOptionPane.showInputDialog());  
sum += n1;  
  
//rest of code for n2 to n8  
  
n9= Integer.parseInt(JOptionPane.showInputDialog());  
sum += n9;  
  
println("The sum of the values you type is " + sum);
```

This works in the sense that we have retained the input data.

BUT...we no longer use loops.

Imagine the code if we had to read in 1,000 numbers?

We need a new approach...

This is where **data structures** come in!

We will now look at **arrays**.

# Arrays (fixed-size collections)

---

- Arrays are a way to collect associated values.
- Programming languages usually offer a special **fixed-size collection** type: an *array*.
- Java arrays can store
  - objects
  - primitive-type values.
- Arrays use a special syntax.

# Primitive types

---

Primitive type

```
int num = 17;
```

Directly stored  
in memory...

17

- We are now going to look at a **structure** that can **store many values** of the **same type**.
- Imagine a structure made up of sub-divisions or sections...
- Such a structure is called an **array** and would look like:

# Structure of a primitive array

---

# Structure of a primitive array

---

**int[] numbers;**

**numbers**

null

# Structure of a primitive array

```
int[] numbers;
```

```
numbers = new int[4];
```

**numbers**

0	0
1	0
2	0
3	0

# Structure of a primitive array

```
int[] numbers;
```

```
numbers = new int[4];
```

We have declared an array of `int`, with a capacity of four.

Each element is of type **int**.

The array is called **numbers**.

**numbers**

0	0
1	0
2	0
3	0

# Structure of a primitive array

```
int[] numbers;
```

```
numbers = new int[4];
```

**numbers**

0	0
1	0
2	0
3	0

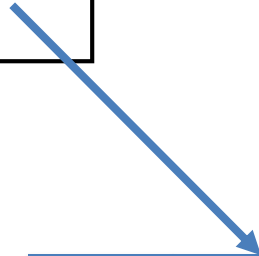

Index of each  
element in the array

# Structure of a primitive array

```
int[] numbers;
```

```
numbers = new int[4];
```

**numbers**

0	0
1	0
2	0
3	0

Default value for each  
element of type **int**.

# Structure of a primitive array

```
int[] numbers;
```

```
numbers = new int[4];
```

```
numbers[2] = 18;
```

We are directly  
accessing the  
element at index **2**  
and setting it to a  
value of **18**.

**numbers**

<b>0</b>	<b>0</b>
<b>1</b>	<b>0</b>
<b>2</b>	<b>18</b>
<b>3</b>	<b>0</b>

# Structure of a primitive array

```
int[] numbers;
```

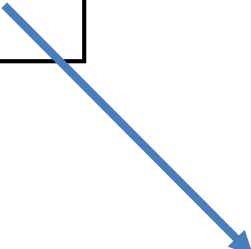

```
numbers = new int[4];
```

```
numbers[2] = 18;
```

```
numbers[0] = 12;
```

We are setting the  
element at index **0**  
and to a value of **12**.

**numbers**

<b>0</b>	<b>12</b>
<b>1</b>	<b>0</b>
<b>2</b>	<b>18</b>
<b>3</b>	<b>0</b>

# Structure of a primitive array

```
int[] numbers;
```

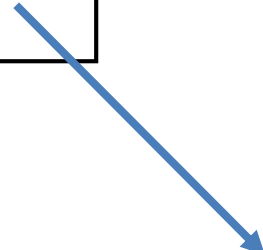

```
numbers = new int[4];
```

```
numbers[2] = 18;
```

```
numbers[0] = 12;
```

```
print(numbers[2]);
```

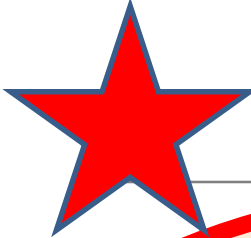

**numbers**

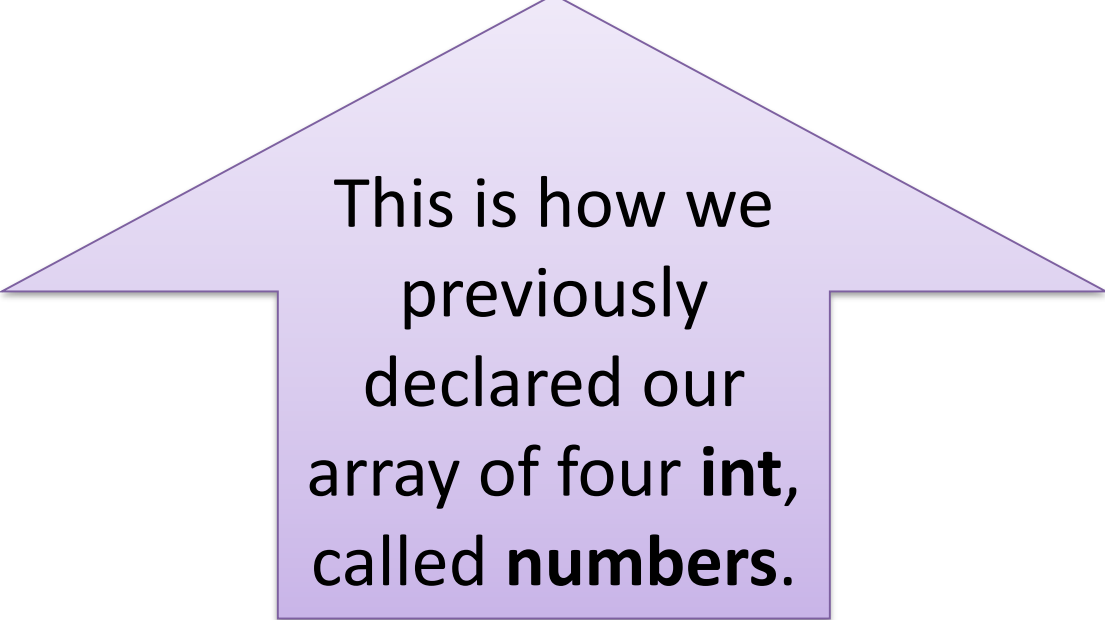

<b>0</b>	<b>12</b>
<b>1</b>	<b>0</b>
<b>2</b>	<b>18</b>
<b>3</b>	<b>0</b>

Here we are printing the contents of  
index location 2  
i.e. 18 will be printed to the console.

# Declaring a primitive array

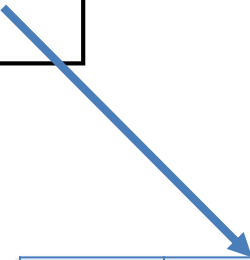

```
int[] numbers;  
//somecode  
numbers = new int[4];
```

This is how we  
previously  
declared our  
array of four **int**,  
called **numbers**.

**numbers**

<b>0</b>	<b>0</b>
<b>1</b>	<b>0</b>
<b>2</b>	<b>0</b>
<b>3</b>	<b>0</b>

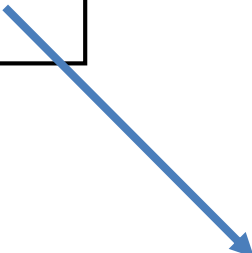

# Declaring a primitive array

```
int[] numbers;  
//somecode  
numbers = new int[4];
```

We can also  
declare it like  
this...

```
int[] numbers = new int[4];
```

**numbers**

<b>0</b>	<b>0</b>
<b>1</b>	<b>0</b>
<b>2</b>	<b>0</b>
<b>3</b>	<b>0</b>

Returning to our method  
that reads in, and sums, 10 numbers  
(typed in from the keyboard)...

and converting it to use primitive arrays...

# Version that doesn't save the numbers

```
import javax.swing.JOptionPane;
```

```
int n;  
int sum = 0;
```

```
for (int i = 0; i < 10; i++) {  
    n = Integer.parseInt  
        (JOptionPane.showInputDialog(  
            "Please enter a number ", "3"));
```

```
    sum += n;
```

```
}
```

```
println("The sum of the values you typed in is : " + sum);
```

Notice that,  
each time a number is read in,  
it overwrites the value stored in **n**.

It doesn't remember  
the individual numbers typed in.

# Using arrays to remember numbers

```
import javax.swing.JOptionPane;
```

```
int numbers[] = new int[10];
```

```
int sum = 0;
```

```
//read in the data
```

```
for (int i = 0; i < 10 : i++) {
```

```
    numbers[i] = Integer.parseInt(JOptionPane.showInputDialog(  
        "Please enter a number ", "3"));
```

```
}
```

```
// now we sum the values
```

```
for (int i = 0; i < 10 : i++) {
```

```
    sum += numbers[i];
```

```
}
```

```
println("The sum of the values you typed in is : " + sum);
```

Using an array  
to store each value  
that was entered.

# Using arrays to remember numbers

```
import javax.swing.JOptionPane;
```

```
int numbers[] = new int[10];
```

```
int sum = 0;
```

```
//read in the data      Loop 1
```

```
for (int i = 0; i < 10 ; i ++) {  
    numbers[i] = Integer.parseInt(JOptionPane.showInputDialog(  
        "Please enter a number ", "3"));  
}
```

```
// now we sum the values      Loop 2
```

```
for (int i = 0; i < 10 ; i ++) {  
    sum += numbers[i];  
}
```

```
println("The sum of the values you typed in is : " + sum);
```

**Q:** Can we reduce the code to only have **one loop**?

Could we move the “sum” code into the first loop?

# Using arrays to remember numbers

**A:** Yes.

**Move the “sum” code into the first loop.**

-> functionality doesn't change

```
import javax.swing.JOptionPane;
```

```
int numbers[] = new int[10];
```

```
int sum = 0;
```

```
//read in the data and sum the values Loop 1
```

```
for (int i = 0; i < 10 ; i ++ ) {
```

```
    numbers[i] = Integer.parseInt(JOptionPane.showInputDialog(  
        "Please enter a number ", "3"));
```

```
    sum += numbers[i];
```

```
}
```

```
println("The sum of the values you typed in is : " + sum);
```

What if we wanted the user  
to decide how many numbers  
they wanted to sum?

```
import javax.swing.*;
```

```
int sum = 0;
```

```
//Using the numData value
```

```
int numbers[];
```

```
int numData = Integer.parseInt (JOptionPane.showInputDialog(  
    "How many values do you wish to sum? ", "3"));
```

```
numbers = new int [numData];
```

```
//read in the data and sum the values
```

```
for (int i = 0; i < numData ; i ++ ) {  
    numbers[i] = Integer.parseInt(JOptionPane.showInputDialog(  
        "Please enter a number ", "3"));  
    sum += numbers[i];  
}
```

```
println("The sum of the values you typed in is : " + sum);
```

1. Declare **numbers** to be an array of type integer.
2. **numData** takes in the size.
3. Use numData to initialize the array with **new** specifying the size.

What type of data  
can be stored  
in a primitive array?

**An array can store ANY TYPE of data.**

### **Primitive Types**

```
int numbers[] = new int[10];
```

```
byte smallNumbers[] = new byte[4];
```

```
char characters[] = new char[26];
```

### **Object Types**

```
String words = new String[30];
```

```
Spot spots[] = new Spot[20];
```

Do we have to use  
**all** the elements in the array?

# Do we have to use all elements in the array?

---

- No.
- **But**...this might cause logic errors, if we don't take this into consideration in our coding.
- Consider this scenario...

## Scenario – exam results and **average grade**

---

- We have a class of 15 students.
- They have a test coming up.
- We want to store the results in an array and then find the average result.

# Average grade

 **results**

0	56
1	65
2	45
3	78
4	98
5	41
6	40
7	55
8	45
9	51
10	42
11	78
12	0
13	0
14	0

We create an array of int with a capacity of 15

Only 12 students sat the exam. Their results were recorded in the first 12 elements

To calculate the average result, divide by the number of **populated elements** **NOT** the array capacity.

# Do we have to use all elements in the array?

---

- If all elements in an array are NOT populated, we need to:
  - have another variable (e.g. int **size**)
    - containing the number of elements in the array **actually used**.
  - ensure size is used when processing the array
    - e.g.  
for (int i= 0; i < **size**; i++)
- For now though, we assume that all elements of the array are populated and therefore ready to be processed.

# Summary - Arrays

---

- Arrays are structures that can store many values of the same type
- Rule – Never lose input data
  - Arrays enable us to store the data efficiently
  - We can use loops with arrays
- Arrays can store ANY type
- Declaring arrays

```
int[] arrayName;  
//somecode  
arrayName= new int[4];
```

OR

```
int[] arrayName= new int[4];
```

# Questions?

---
